Introduction

After having attended the classes and successfully completed the workshops of this course, you now know what CCH Tagetik is, why and how it is used on a daily basis.
To finalize the training and put all of the acquired knowledge into practice, you will be asked to complete a Business Case.
While workshops are meant for you to learn how to use specific CCH Tagetik features, the Business Case requires you to decide, on the basis of given requirements, the actions to be taken when doing a business project, as well as to check whether such actions were correct.

Context

You are working (as user **EMPEROR**, password **tgk**) in a preconfigured environment in which the customer needs to meet a series of mandatory requirements for a new project.
This means that some part of the work is done (e.g., process, scenario, account) but some mandatory requirements must be fulfilled.
Each requirement is considered accomplished only if each sample object provided in Mandatory requirements below is faithfully reproduced in CCH Tagetik.
On top of these mandatory requirements, some additional requests have been made to fine-tune the application (Optional requirements). These requests would improve the overall usability of the application but are not vital for its functioning.
As a result, try first to fulfill all the minimum requirements. Then, if you still have time left, take care of the optional ones.
In order to meet the requirements, remember to take as a reference the files provided in the proper folder (e.g. when deciding which fields to create into a dataset, or how to apply the correct layout to a form); in some cases, you should create a code/description of your choice of a Tagetik element (e.g. a new workspace or a new workflow task).
Since some parts of the environment can be customized, you should focus on the result expected by the customer.
You should work independently; however, you can ask the trainer for help and three checkpoints have been scheduled to make sure nobody gets lost.
At the end of the Business case, you will be able to present it to your customers, as it happens in real projects.

Business case workflow

Analysis

A business project always starts with an analysis phase. Based on the files provided, the database and the mandatory requirements, it is necessary to understand what elements are missing in the workspace to satisfy your customer's needs. It is highly recommended to collect all the requirements and to make a to-do list in chronological order. This is a fundamental step, so take your time to do it.

Data model

After the analysis, it is necessary to create all the missing elements in the application; consider you have the files available to build the data model, whereas regarding some elements (Analytical workspace) you need to invent the code according to the business project.
In order to create the data model, it is recommended to follow this workflow:

- Create the dimensions
- Add a new Analytical workspace
- Set up the related datasets

Data collection and reporting

It is now time to collect data with different data collection tools and display them through Reporting:

- You will have to review your business workflow (**ROYALTIES**) and run your process task accordingly. Please remember that the process cockpit **(2030ACT)** should translate the customer's business requirements into the CCH Tagetik application
- You will then proceed with collecting your data. You will collect most of your data via Quick data loader (Qdl), which will populate the datasets you created. However, some data will have to be calculated on the fly. You will do this by using a Data transformation package (DTP)
- Once your data have been properly collected and calculated, you will have to create output and input forms, so that customers will be able to view and update as they please
- Please note that forms features will differ greatly, and that one form will require you to map data that is located in the Analytical workspace to the Financial Workspace. To do this, you will have to perform a Financial workspace mapping

- When Data collection is finished, remember to run the data submission to lock the data entry for all accounts mapped in the process data model

Project mandatory requirements

IMPORTANT: You can find all the necessary files below the folder **Workshops - Business case**

Who?

The customer is Spotishop, a company founded in 2013 in Northern Ireland that offers digital copyright restricted recorded audio content, including more than 10 million songs.

What?

Starting from **December 2030**, they need to calculate the royalties to be paid to the best performing singers and band by the geographical market, based on the number of plays.

Data model:

Find attached the following documents:

- List of Singers and Band.xlsx
- List of Geographic Market.xlsx

HINT: Since the lists represent two different dimensions, consider that the geographical market must be used for the financial workspace and you need to create a Custom Dimension. Bear in mind that you must not import the details on column “Music genre "since this column displays how to structure the Hierarchy.

Spotishop asks for a separate workspace to manage this project. Below you can find the files name containing the data to upload into the system:

- Royalties.xlsx
- Listening data.xlsx

HINT:

- The two files provided correspond to two different tables; pay attention to the columns and the data type.
- To create fields in the dataset, they must be OFFLINE. To upload data, datasets must be ONLINE.
- Remember to run a general deployment before uploading data

Checkpoint 1

Data collection and reporting:

Starting from the files provided the customer requires to upload data and then calculate the product of royalties and number of plays (**Royalties * number of plays)**

HINT:
Access the process cockpit **2030ACT** to upload data into the datasets.

To ensure a correct calculation, remember to create:

- a new dataset in which the data will be calculated
- a new dataset typology
- a data transformation package (DTP) with insertion, enrichment, and formula (remember to tick the option Empty dataset and Update Reporting layer)
- the new DTP task into the existing workflow

To fulfill the requirements, the database should provide some new forms, namely:

- **Royalties**

A data entry form that replicates the structure of the form “Royalties” provided

HINT: be aware of the structure of the form, if it is similar to the dataset created you can automatically create it from the dataset (Action menu > Data entry form)

- **Listening data**

A data entry form that replicates the structure of the form “Listening data” provided

HINT: be aware of the structure of the form, if it is similar to the dataset created you can automatically create it from the dataset (Action menu > Data entry form)

Checkpoint 2

- **Royalties Calculation**

This form displays the royalties calculated by listening data and has the following structure:

Row = Singers and band
Columns = Geographical markets

Furthermore, in order to see all the data converted into a single currency based on the Final FX Rate, it is required to set up an on-the-fly conversion.

The data must be able to be updated automatically in the event that a Singers/band or a Market is created on the web application.

HINT:

- Set-up a conversion based on the measures (remember to change the Conversion type into the dataset to final fx rate).
- Add the new Fx rates following the file provided
- Leverage the dynamicity option to automatically retrieve data from an aggregation structure.

• Profit and Loss

This is a data entry form that displays the profit and loss of the company (financial data) in which the accounts, already present in the web application, are shown.
It is required to use a replicable and functional structure because the rows structure of this form will be used in other forms; the data about Royalties are fed by the Analytical Workspace.
Put this form below a new folder named **Profit & loss.**

HINT:

- Since the Accounts is not a dimension reported in the datasets created, consider adding a new form based on the Financial workspace.
- To replicate an account structure easily, you should create an FST, following the rows of the form provided.
- Create a Financial workspace mapping to update **BC030 - Royalties** data.
- Pay attention to the account sign.
- Bear in mind that you can upload data by qdl or manually by input data entry form. If you cannot see the form in data entry modality, add it into the process (**Process data model** section). Please note that during the mapping of the QDL you need to:
    - Remove the relationship between Market and default value GEN_M and drag and drop the column with values.
    - Set the deletion policy as “No Deletion”

Checkpoint 3

Optional requirements

If you fulfilled all the mandatory requirements, you could improve the application with the following enhancements.
Create a new folder

- **Profit & Loss**: restrict the possible selection of the scenario parameter to the 2030ACT only
- **Profit & Loss**: restrict the possible selection of the period parameter to the 2030ACT only
- Customize the end user homepage emphasizing the work done so far and making it as pleasant as possible
- Prepare a quick PowerPoint presentation of the project
